tJoin is a basic pure component used to do a join, including inner join and left outer join, between two data sources. tMap is more powerful in terms of functionality than tJoin, though tMap can be used to perform the same functionality as tJoin, but they are different components and are designed for different needs.

Below is the list of the differences between tJoin and tMap:

tMap can have many output links compared to tJoin which only has a main and reject links.

tMap supports for writing expression on the columns while providing the joining condition, however, tJoin only supports exact match between the keys.

tMap supports the storage of the look-up data on disk.

tMap allows you to reload the look-up data for each main record.

tMap supports more types of join model, includes unique join, first join and all join.
